# CSE232: Database System Principles

#### **Hardware**

1

### **Database System Architecture**

#### Memory Hierarchy

- Cache memory
   On-chip and L2
   Caching outside
  - Caching outside control of DB system
- Increasingly important comments
- RAM (controlled by db system)
  - Addressable space includes virtual memory but DB systems avoid it
- SSDs
- Block-based storage
- Disk
  - Block
  - Preference to sequential access
- Tertiary storage for archiving
  - Tapes, jukeboxes, DVDs
  - Does not matter any more

Cost per byte  Access Speed	Capacity Capacity	Capacity	Cost per byte	Ess L
-----------------------------	-------------------	----------	---------------	-------

1

#### Non-Volatile Storage is important even when RAM is large • Persistence important for transaction atomicity and durability • Even if database fits in main memory changes have to be written in nonvolatile storage · Hard disk RAM disks w/ battery Flash memory Peculiarities of storage mediums affect algorithm choice Block-based access: - Access performance: How many blocks were accessed How many objects - Flash is different on reading Vs writing • Clustering for seguential access: - Accessing consecutive blocks costs less on disk-based systems · We will only consider the effects of block access Moore's Law: Different Rates of Improvement Lead to Algorithm & **System Reconsiderations** Processor speed Clustered/sequential Rate access-based algorithms • Main memory bit/\$ for disk became relatively Disk bit/\$ better Disk Transfer · RAM access speed

 Disk access speed • Disk transfer rate

## Moore's Law: Same Phenomenon Applies to RAM Algorithms that access memory sequentially Rate have better constant factors than algorithms that access randomly **RAM Transfer** Moore's Law: Different Rates of Improvement => **Different Buffering Considerations** Cost of "miss" increases Cache Capacity RAM Capacity 2-Phase Merge Sort: An algorithm tuned for blocks (and sequential access) RAM buffer PKAD LEZWJCRHYFXI ← file key record Assume a file with many records. Each record has a key and other data. For ppt brevity, the slide shows only the key of each record and not its data.

Assume each block has 2 records.
Assume RAM buffer fits 4 blocks (8 records)
In practice, expect many more records
per block and many more records fitting in buffer.

**Problem:** Sort the records according to the key. **Morale:** What you learnt in algorithms and data structures is not always the best when we

consider block-based storage

#### 2-Phase Merge Sort PKAD LEZWJCRH YFXI Phase 1, round 1 READ RAM buffer PKADLEZW Secondary storage SORT in place, eg quicksort ADEKLPWZ WRITE ADEKLPWZ 2-Phase Merge Sort PKADLEZWIJCRHYFXII Phase 1, round 2 Phase 2 continues until no more records READ Secondary storage RAM buffer ADEKLPWZ JCRHYFXI SORT 1st file CFHIJRXY WRITE CFHIJRXY 2<sup>nd</sup> file In practice, probably many more Phase 1 rounds and 11 many respective output files 2-Phase Merge Sort PKADLEZWJCRH YFXI Phase 2 Assume #files < #blocks that fit in RAM buffer. Fetch the first block of each file in RAM buffer. Merge records and output. When all records of a block have been output, bring next block of same file ADEKLPWZ ACDE ... CFHIJRXY Improvement: Bring max number of blocks in memory.

## 2-Phase Merge Sort: Most files can be sorted in just 2 passes! Assume • M bytes of RAM buffer (eg, 8GB) • B bytes per block (eg, 64KB for disk, 4KB for SSD) Calculation: • The assumption of Phase 2 holds when #files < M/B => there can be up to M/B Phase 1 rounds • Each round can process up to M bytes of input data => 2-Phase Merge Sort can sort M<sup>2</sup>/B bytes $- \text{ eg } (8GB)^2/64KB = (2^{33}B)^2 / 2^{16}B = 2^{50}B = 1PB$ Horizontal placement of SQL data in blocks Relations: • Pack as many tuples per block - improves scan time · Do not reclaim deleted records • Utilize overflow records if relation must be sorted on primary key • A novel generation of databases features column storage - to be discussed late in class 14 Pack maximum #records per block

3 PL   CSE130   TuTh   9:00   9:50	
Overflow block	16

#### **Block Size Selection?**

ullet Big Block ightarrow Amortize I/O Cost

• Big Block  $\Rightarrow$  Read in more useless stuff! and takes longer to read

17

# The future (which has partly arrived)

- Entire (analytics) databases in RAM
- Multi-core CPUs
  - case of parallel query processing
- Non-Volatile RAM

3
